## Description

### BACKGROUND OF THE INVENTION

Astigmatism is a defect in the eye that is corrected by a lens with a non-spherical prescription. The prescription, which is usually expressed as cylinder on the patient's prescription order, causes at least a portion of the surface of the lens to have the shape of a toric segment. Hence, such lenses are called toric lenses. The corrective lens must be properly oriented with respect to the eye of the wearer. That is, the intended top of the lens must be at the top of the wearer's eye. For ordinary glasses this presents no problem, because the lens is permanently fixed to the frame at the correct rotational orientation. The ear and nose pieces of the frame assure that the frame and the lens do not rotate with respect to the wearer's eyes. For contact lenses orientation is subject to constant alteration. In the case of contact lenses whose function is to correct astigmatism this is unacceptable.

Soft contact lenses which have been designed for use to correct astigmatism are well known in the art. Generally these lenses rely on some type of ballasting method to cause the lens to ride at the proper location on the eye. An ideal lens for correcting astigmatism has three properties:

(1) Good rotational orientation. That is, as stated above, the intended top of the lens should be located at the top of the wearer's eye when the lens is worn. A small amount of deviation from the correct orientation can be tolerated, provided the lens fitter measures the deviation and takes it into account in the lens's prescription.

(2) Good rotational stability. That is, the lens should remain at a fixed rotational orientation within the eye during the entire wearing period. Furthermore, the lens should assume the same orientation each time it is worn.

(3) Comfort. In general the thinner the lens and the smoother the lens surface, the more comfort it will provide.

Lenses in accordance with this invention are preferably soft contact lenses, which may be formed of many materials including hydroxyethylmethacrylate, metallo-organic substances, silicone rubbers and various other materials such as described in U.S.-A-3,503,942 and 3,639,524. The preferred soft contact lenses are hydrophilic; that is, they absorb water and, in fact, the water becomes an integral part of their structure. Hydrophilic contact lenses made in accordance with U.S.-A-4,405,773 are especially preferred for practicing this invention.

U.S.-A-4,084,890, discloses a contact lens which is

alleged to have improved adherence to the cornea and improved visual acuity as a result of its configuration. The lens tapers from a thin outer edge to an intermediate point of maximum thickness and then tapers to the center of the lens. The peripheral surface portion is wedge shaped in cross section. However this lens is believed to be uncomfortable because of its thickness.

U.S.-A-4,095,878, discloses a contact lens which maintains the correct orientation when placed on the eye as a result of a flattened portion on the periphery. In one embodiment the lens is symmetrical about the horizontal axis. The lens is thinnest at its vertical axis and increases in thickness along the flattened section in both directions from the vertical axis, having its thickest portion at the horizontal axis. While the disclosed lens has rotational stability, the lens of the present invention is expected to have better rotational stability.

U.S.-A-4,324,461, discloses a contact lens for correcting astigmatism which is alleged to provide the proper rotational positioning. The lens has a thickness disparity between the superior (top) and inferior (bottom) portions of the lens and a thicker ballast portion is provided at the inferior portion. However the thicker ballast portion of the lens is believed to cause discomfort compared to the lens of the present invention.

While the posterior surface of a contact lens is generally spherical in configuration, where the lens is to be used to correct astigmatism it will have a toric configuration. That is, the curved portion of the posterior of the lens has a major and minor axis; the radius of curvature of the posterior surface of the lens being longer in the major-axis direction than in the minor-axis direction. The result is that rather than being of a spherical configuration, the posterior of the lens has a toric configuration with the major axis running orthogonal to the minor axis. The major diameter of the toric curve is generally smaller in diameter than the overall lens, and is cut into a starting base curve which has a spherical configuration.

In the toric lenses of the prior art the junction between the base curve of the posterior surface of the lens and the toric curve portion is in an area of sharp inflection resulting in a sometimes uncomfortable fit to the cornea.

### SUMMARY OF THE INVENTION

It has surprisingly been found that a contact lens of improved rotational stability, rotational orientation and comfort can be prepared by configuring the lens so that it has a greater thickness in its lower portion, the lens being symmetrical about its vertical axis on its anterior surface. The comfort to the wearer of the lens is improved by having a gradual change in curvature between the base curve portion of the posterior of the lens and the toric curve.

In detail, the present invention relates to a contact lens (1) of general concavo-convex configuration having improved rotational stability and rotational orientation wherein the anterior surface of said lens comprises a

central optical zone (2) and an outer carrier having a generally tapered surface with a thin portion (101) at the upper edge of the lens and two points (6,6') of maximum thickness located at oblique angles,  $\alpha$ , of  $110^\circ$  to  $130^\circ$  as measured from the vertical axis (AA) from the top of the lens; the anterior surface of said lens being symmetrical about the vertical axis, the carrier tapering from the points of maximum thickness to a thin portion (101) located at the top of the lens and to a thin portion (100) located at the lower edge of the lens in a smooth curve, and the carrier tapering in a smooth curve along the vertical axis from the optical zone to the bottom of the lens and wherein the posterior surface of said lens comprises a generally concave shape having a toric configuration, said lens having a gradual change in curvature between the base curve portion of the posterior of the lens and the toric curve.

In a preferred embodiment of the invention the lens has a posterior surface comprising:

- (a) an outer annular spherical base curve zone;
- (b) an inner toric zone having a major meridian and a minor meridian orthogonal to each other; and
- (c) a transition zone between the toric zone and the base curve zone having thickness that gradually increases from the base curve zone to the toric zone; wherein the radius of the base curve zone is substantially equal to the radius of the major meridian; the intersection of the minor meridian and the transition zone is located no more than 0.12mm below an imaginary extension of the spherical base curve zone passing above that intersection; and the intersection of the major meridian and the transition zone is located no more than 0.07 mm below an imaginary extension of the spherical base curve zone passing above that intersection.

The invention is especially suitable for hydrophilic contact lenses which are normally shaped in the dry state and then hydrated. Upon hydration, such lenses expand. All dimensions given in the specification and claims are for a full sized lens; i.e., for a hydrophilic lens, a fully hydrated lens; unless specifically stated to be for a lens in the dry state.

#### BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a view of the anterior surface of the lens.

Figure 2 is a sectional view of the lens of figure 1 taken along section A-C, wherein the portion of section A-C from the lens center to C has been rotated so that A-C is a straight line.

Figure 3 is a sectional view of the lens showing its anterior surface taken along the major axis of the lens's toric curve.

Figure 4 is a sectional view of the lens showing its anterior surface taken along the minor axis of the lens's toric curve.

Since Figures 3 and 4 are intended to show only the preferred posterior surface of the lens, the details of the anterior surface do not appear in those figures.

Figure 5 is a view of the preferred posterior surface of the lens.

Figure 6 is a sectional view of the edge of the lens of this invention showing details of an optional edge configuration.

#### DETAILED DESCRIPTION OF THE INVENTION

As used in the specification and claims the term "vertical" is used with reference to the lens as it would be, if ideally seated on the cornea of eye without any shift in orientation resulting by movement caused by the eye lid. The vertical axis is represented in Figure 1 by the center line A-A.

Referring to Figure 1, which shows the anterior surface of the lens, the lens, 1, has a central optical zone, 2, which is formed by known prior art techniques. The optical zone is surrounded by a carrier portion as in the prior art. The configuration of this carrier portion of the lens, however differs from the prior art as hereinafter described. Curves 3, 4 and 5, represent portions of the surface of the carrier portion as formed in the manner described below, to form the anterior surface of the lens. While these curves appear to delineate distinct areas of the lens they are shown for clarity of description of the invention only. It will be appreciated by those skilled in the art that there are no sharp distinctions between these different sections of the carrier portion of the lens, but that they are smoothly blended into one another.

The thickest portion of the lens is located at points, 6 and 6'. All references to point, 6, are applicable to point, 6', since the lens is symmetrical about center line A-A on its anterior surface. Point, 6, is located on the center line B-C at the intersection of curves 3, 4 and 5. It is located on a line along center line B-C at an angle,  $\alpha$ , from the vertical. The angle,  $\alpha$ , is the included angle designated by the bent lines A-C and A-C'. The angle,  $\alpha$ , should be  $110^\circ$  to  $130^\circ$ ; more preferably  $115^\circ$  to  $125^\circ$ ; most preferably  $120^\circ$ . The angle,  $\alpha$ , is measured from the top of the lens which is at  $0^\circ$ . While the location of 6, is referred to as a point, it will be appreciated by those skilled in the art that there is no sharp inflection at this point, but as stated above the anterior surface of the lens is a smooth curve. In a preferred embodiment point, 6, is located on a radius at a distance of 0.7 to 1.5 mm in from the edge of the lens, 8, most preferably 1 mm.

Figure 2, is a sectional view along Section A-C (Figure 1) showing the anterior surface of the lens. Figure 2 shows the view that would be seen if line A-C of figure 1 were to be straightened. The anterior surface of the inventive lens is formed by first rotating it about central axis, O-O, to cut a concentric trim, 7. The concentric trim, 7, results in a thinner edge section of the lens with more comfort to the wearer. As used in the specification and claims the term "concentric trim" means the aforede-

scribed concentric thinned section of the lens. It is an optional improvement in the lens of this invention, but where it is utilized, it is the first section cut. The cutting is accomplished by the prior art technique of swinging the cutting tool through a fixed circular arc while rotating the lens. The concentric trim, as it appears in the finished lens, is located between the outer edge 8 of the lens and curves 3 and 4 (see Figure 1).

The lower portion 100 of the carrier of the lens is then cut by shifting the axis of the lens along the vertical center line, A-A (Figure 2), a distance, a, to the position shown by rotation axis, K-K displaced toward the upper section of the lens. Rotation about Axis K-K while cutting generates the lower portion 100 of the carrier which tapers in a smooth curve along vertical axis AA from the optical zone to the bottom of the lens, as best seen in figure 1. The axis of the lens is then shifted along the vertical center line, A-A, a distance, b, from the central axis, O-O, toward the lower portion of the lens to a new axis of rotation, I-I, to cut the upper section 101 of the carrier. Where distances a and b are equal, the point, 6, is on a horizontal axis of the lens ( $\alpha = 90^\circ$ ). In order that  $\alpha$  be greater than  $90^\circ$  the distance, a, must be greater than the distance, b. Preferably b is 0.1 to 0.4 mm and a is 0.2 to 1.2 mm.

The optical zone, 2, is cut in the manner of the prior art. It is usually spherical in configuration, but it can have a toric configuration. The radius of curvature will depend on the prescription of the user. All of the axes of rotation including that used to cut the optical zone are on the vertical center line A-A.

Referring now to Figure 3, in cutting the preferred posterior surface of the lens of this invention a base curve is cut into the posterior surface of the lens. Unlike the prior art, however, this base curve is constructed of two distinct zones, a spherical base curve zone 11 and a pad zone 10. The pad zone is made up of pad curve 13 and a transition zone 9. The radius of the base curve zone 11 on an outer annulus of the lens is approximately equal to the radius that the toric section of the lens is to have along its major meridian. This is much different from the prior art wherein the radius of the base curve, which initially extends over the entire anterior surface of the prior art lens is longer than the radius which the toric section is to have in its major meridian. Pad curve 13 is cut into the lens at a radius that is smaller than the radius of base curve zone 11 by 0.08 to 0.15 mm, preferably 0.1 mm. Curves 13 and 11 have the same center of curvature. Transition zone 9 is 0.5 to 1.5 mm wide, and in cross section is essentially a linear ramp connecting base curve zone 11 with pad curve 10. Curves 13 and 9 are both spherical. Thus the thickness of the transition zone generally increases from base curve zone 11 to pad curve 13.

A toric curve, 14, whose dimensions are determined by the prescription, is then cut into the previously described posterior surface. As described above this toric curve has a major and minor axis. The radius of curva-

ture of the major curve of the major meridian is generally the same as that of the base curve zone 11. This major median of the toric curve may lie on vertical line A-A (Figure 5). However, alternatively, it may be an oblique angle to that line depending on the user's prescription or the rotation of the lens resulting from movement caused by the eye lid, or both. In cutting the major meridian of the toric curve, 14, the depth of cut is controlled so that it intersects the transition zone 9 near its outer edge, 12, as best seen in figure 5 along axis A-A. Referring to Figure 5, the outer edge of the transition zone, 12, is the outer edge of the pad zone 10. Generally, the major meridian 15 of the toric curve will be slightly smaller than the outer dimension of the pad zone. Preferably, the major meridian of the toric curve is 0.03 to 0.5 mm smaller than the pad zone diameter. The minor meridian, 15', of the toric curve which is at right angles to the major meridian and may lie on line E-E, is less than the pad zone diameter by 0.2 to 2.5 mm.

Figure 4 is a sectional view showing the preferred posterior lens configuration taken along the minor axis of the toric curve, i.e. along section E-E of figure 5. Here the outer edge 17 of the minor axis can be seen, as well as the edge 16 of the pad zone, and pad curve 13. This configuration results in a smoother blend between the transition zone 9 and toric curve 14 as contrasted with the prior art which has a steeper inflection point between the toric curve and the base curve.

For lenses in accordance with the preferred aspect of this invention, the intersection of the minor meridian 17 and transition zone 9 is located no more than 0.12 mm below an imaginary extension of spherical base curve zone 11 passing above that intersection. Preferably this intersection will be between 0.04 and 0.12 mm below the imaginary extension of the spherical base curve zone. Furthermore, the intersection of the major axis 15 and transition zone 9 will be located no more than 0.07 mm below an imaginary extension of spherical base curve zone 9. For prescription, wherein the outer edge of the toric curve at the major meridian and the outer edge of transition zone 9 coincide, the intersection will be located on spherical base curve zone 9.

The configuration of the preferred posterior of the lens of this invention results in a lens which along its vertical meridian is thinner at the junction of the carrier with the optical zone than prior art lenses and thus is thinner in the carrier as a whole. This results in a lens which on average is lighter in weight. Prior art lenses are about 0.18 mm in thickness in the dry state at their thickest point along the vertical meridian. The lenses of the preferred aspect of this invention will range in maximum thickness from 0.13 to 0.15 in the dry state at the corresponding point.

The intersection of the outer edge of the toric curve with the transition zone is more obtuse than that between the toric curve and the base curve of the prior art. The more obtuse junction contributes to greater lens comfort, and lessens the possibility that the lens will make a pres-

sure indentation on the corneal surface. This contributes both to comfort because of reduced weight, and to improved oxygen transmissibility of the lens, thereby improving corneal health.

The edge thickness 19 of the lens as shown in Figure 6, is 0.03 to 0.11 mm. This edge, optionally, is displaced from the base curve zone, 10, by an edge lift, 18, of 0.05 to 0.12 mm. The effect of the lift is to give a more comfortable feel to the wearer of the lens. The edge thickness, 19, of the lens of this invention as measured at the edge of the lens, 8, is generally thinner than that of the prior art as a result of the concentric trim, previously described.

While the manufacture of the lens of this invention has been described in terms of cutting of the various curves, it will be appreciated by those skilled in the art having access to this disclosure that the configuration of the anterior of the lens and the base curve as well as the pad of the posterior of the lens can be formed by molding the lens in an appropriately shaped cavity mold.

#### Claims

1. A contact lens (1) of general concavo-convex configuration having improved rotational stability and rotational orientation wherein the anterior surface of said lens comprises a central optical zone (2) and an outer carrier having a generally tapered surface with a thin portion (101) at the upper edge of the lens and two points (6,6') of maximum thickness located at oblique angles,  $\alpha$ , of  $110^\circ$  to  $130^\circ$  as measured from the vertical axis (AA) from the top of the lens; the anterior surface of said lens being symmetrical about the vertical axis, the carrier tapering from the points of maximum thickness to a thin portion (101) located at the top of the lens and to a thin portion (100) located at the lower edge of the lens in a smooth curve, and the carrier tapering in a smooth curve along the vertical axis from the optical zone to the bottom of the lens and wherein the posterior surface of said lens comprises a generally concave shape having a toric configuration, said lens having a gradual change in curvature between the base curve portion of the posterior of the lens and the toric curve.
2. The contact lens according to claim 1 wherein the maximum thickness of the lens is located on radii (C, C') passing through the center of the lens at points 0.7 to 1.5 mm from the edge of the lens.
3. The contact lens according to claim 1 or 2 wherein the angle,  $\alpha$ , is  $115^\circ$  to  $125^\circ$ .
4. The contact lens according to claim 3 wherein the angle,  $\alpha$ , is  $120^\circ$ .

5. A contact lens according to any one of claims 1 to 4 wherein the concave posterior surface comprises:

- (a) an outer annular spherical base curve zone (11);
- (b) an inner toric zone (14) having a major meridian (15) and a minor meridian (15') orthogonal to each other; and
- (c) transition zone (12) between the toric zone (14) and the base curve zone (11) having thickness that gradually increases from the base curve zone to the toric zone;

wherein the radius of the base curve zone (11) is substantially equal to the radius of the major meridian (15); the intersection (17) of the minor meridian (15') and the transition zone is located no more than 0.12 mm below an imaginary extension of the spherical base curve zone (11) passing above that intersection; and the intersection of the major meridian (15) and the transition zone (12) is located no more than 0.07 mm below an imaginary extension of the spherical base curve zone passing above that intersection.

6. A contact lens in accordance with claim 5 wherein the intersection of the minor meridian (15') and the transition zone (12) is located from 0.04 to 0.12 mm below an imaginary extension of the spherical base curve zone.

#### Patentansprüche

1. Kontaktlinse (1) mit konkavkonvexer Hauptkonfiguration mit verbesserter Drehstabilität und Drehorientierung, wobei die vordere Oberfläche der Linse eine mittlere optische Zone (2) und einen äußeren Träger mit einer im allgemeinen konusförmigen Oberfläche mit einem dünnen Teil (101) an der oberen Kante der Linse und zwei Punkten (6,6') maximaler Dicke umfaßt, die sich an schiefen Winkeln  $\alpha$  von  $110^\circ$  bis  $130^\circ$ , von der vertikalen Achse (AA) von der Oberseite der Linse aus gemessen, befinden; wobei die vordere Oberfläche der Linse symmetrisch in Bezug auf die vertikale Achse ist, wobei der Träger sich von den Punkten der maximalen Dicke bis zu einem dünnen Teil (101), der sich an der Oberseite der Linse befindet, und zu einem dünnen Teil (100), der sich an der unteren Kante der Linse befindet, in einer glatten Kurve verjüngt, und wobei der Träger sich in einer glatten Kurve entlang der vertikalen Achse von der optischen Zone bis zum Unterteil der Linse in einer glatten Kurve verjüngt, und wobei die hintere Oberfläche der Linse eine im allgemeinen konkav

Form mit einer torischen Konfiguration aufweist, wobei die Linse zwischen dem Grundteil der Biegung an der Hinterseite der Linse und der torischen Kurve eine graduelle Änderung der Krümmung aufweist.

2. Kontaktlinse nach Anspruch 1, wobei die maximale Dicke der Linse sich an den Radien (C, C') befindet, die an Punkten durch die Mitte der Linse gehen, die 0,7 bis 1,5 mm von der Kante der Linse entfernt sind. 10
3. Kontaktlinse nach Anspruch 1 oder Anspruch 2, wobei der Winkel  $\alpha$  115° bis 125° beträgt.
4. Kontaktlinse nach Anspruch 3, wobei der Winkel  $\alpha$  120° beträgt. 15
5. Kontaktlinse nach einem der Ansprüche 1 bis 4, wobei die konkave hintere Oberfläche umfaßt: 20
  - (a) eine äußere ringförmige sphärische Basis-  
kurvenzone (11);
  - (b) eine innere torische Zone (14) mit einem  
Hauptmeridian (15) und einem Nebenmeridian (15'), die senkrecht zueinander sind; und 25
  - (c) eine Übergangszone (12) zwischen der torischen Zone (14) und der Basiskurvenzone (11) mit einer Dicke, die graduell von der Basiskurvenzone bis zur torischen Zone anwächst; wobei der Radius der Basiskurvenzone (11) im wesentlichen gleich dem Radius des Hauptmeridians (15) ist; der Schnittpunkt (17) des Nebenmeridians (15') mit der Übergangszone sich nicht mehr als 0,12 mm unter einer imaginären Verlängerung der sphärischen Basiskurvenzone (11), die über diesen Schnittpunkt geht, befindet; und wobei der Schnittpunkt des Hauptmeridians (15) mit der Übergangszone (12) sich nicht mehr als 0,07 mm unter einer imaginären Verlängerung der sphärischen Basiskurvenzone, die über diesen Schnittpunkt geht, befindet. 40
6. Kontaktlinse nach Anspruch 5, wobei der Schnittpunkt des Nebenmeridians (15') mit der Übergangszone (12) sich 0,04 bis 0,12 mm unterhalb einer imaginären Verlängerung der sphärischen Basiskurvenzone befindet. 50

#### Revendications

1. Lentille de contact (1) de considération générale-  
ment concave-convexe ayant une meilleure stabilité  
à la rotation et une meilleure orientation à la rotation  
ou la surface antérieure de ladite lentille comprend 55

une zone optique centrale (2) et un support externe  
ayant une surface généralement effilée avec une  
portion mince au bord supérieur de la lentille et deux  
points (6,6') d'épaisseur maximale placés à des  
angles obliques,  $\alpha$ , de 110° à 130° en mesurant à  
partir de l'axe vertical (AA) à partir du sommet de la  
lentille; la surface antérieure de la lentille étant  
symétrique autour de l'axe vertical, le support s'effi-  
lant à partir des points d'épaisseur maximale jusqu'à  
une portion mince (101) placée au sommet de la len-  
tille et jusqu'à une portion mince (100) placée au  
bord inférieur de la lentille en une courbe régulière  
et le support s'effilant en une courbe régulière le long  
de l'axe vertical à partir de la zone optique jusqu'au  
bas de la lentille et où la surface postérieure de ladite  
lentille comprend une forme généralement concave  
ayant une configuration torique, ladite lentille ayant  
un changement graduel de courbure entre la portion  
de courbe de base de la partie postérieure de la len-  
tille et la courbe torique.

2. Lentille de contact selon la revendication 1 où  
l'épaisseur maximale de la lentille est placée sur les  
rayons (C,C') passant à travers le centre de la lentille  
aux points de 0,7 à 1,5 mm à partir du bord de la  
lentille.
3. Lentille de contact selon la revendication 1 ou 2, où  
l'angle,  $\alpha$ , est de 115° à 125°.
4. Lentille de contact selon la revendication 3, où  
l'angle,  $\alpha$ , est de 120°.
5. Lentille de contact selon l'une quelconque des  
revendications 1 à 4, où la surface postérieure con-  
cave comprend :

(a) une zone de courbe de base sphérique  
annulaire externe (11);

(b) une zone interne torique (14) ayant une  
méridienne majeure (15) et une méridienne  
mineure (15') orthogonales l'une à l'autre; et

(c) une zone de transition (12) entre la zone tori-  
que (14) et la zone de courbe de base (11) ayant  
une épaisseur qui augmente graduellement à  
partir de la zone de courbe de base jusqu'à la  
zone torique;

où le rayon de la zone de courbe de base (11)  
est sensiblement égal au rayon de la méri-  
dienne majeure (15); l'intersection (17) de la  
méridienne mineure (15') et de la zone de tran-  
sition est placée à pas plus de 0,12 mm en des-  
sous d'une extension imaginaire de la zone de  
courbe de base sphérique (11) passant au-des-  
sus de cette intersection; et l'intersection de la

méridienne majeure (15) et de la zone de transition (12) est placée à pas plus d 0,07 mm en dessous d'une extension imaginaire de la zone de courbe de base sphérique passant au-dessus de cette intersection.

5

6. Lentille de contact selon la revendication 5 où l'intersection de la méridienne mineure (15') et de la zone de transition (12) est placée entre 0,04 et 0,12 mm en dessous d'une extension imaginaire de la zone de courbe de base sphérique.
